

docufi3d Usability Study

Evaluation of User Feedback

Study period: July-August 2025

Participants: 30

Completed questionnaires: 25

Incomplete questionnaires: 5

Completion rate: 83.3%

This report summarizes the usability feedback collected during the docufi3d user study. The study examined how easily users could access the service, navigate the platform, prepare and sign documents, use the pay-per-use model and complete available payment processes.

Overall study result: The core docufi3d experience was perceived as smooth and user-friendly. The main improvement area was QES onboarding. Pay-per-use worked well, while ADA payments were functional but perceived as too slow.

1. Purpose and Scope

The usability study was conducted in July and August 2025 to evaluate the accessibility, usability and overall user-friendliness of docufi3d. The objective was not only to determine whether individual functions worked technically, but also whether users could understand the service and progress through the relevant workflows without significant friction.

Particular attention was given to the points at which a user first enters the service and moves through the electronic-signature journey. These access points included getting started, initial onboarding, navigation, document upload and preparation, electronic signing, QES onboarding, pay-per-use and payment. ADA payment was evaluated separately because its blockchain-based confirmation process differs from conventional online payment experiences.

The study therefore provides an initial view of both the strengths of the docufi3d user journey and the areas in which additional process steps created noticeable friction.

2. Participation and Evaluation Basis

30	25	5	83.3%
Participants	Completed	Incomplete	Completion rate

A total of 30 users participated in the usability exercise. Twenty-five participants completed the questionnaire in full; five questionnaires remained incomplete. The qualitative evaluation presented in this report is based on the 25 completed questionnaires (n = 25).

The survey used a five-point response format across ten usability dimensions, supplemented by an optional free-text field. The detailed individual response records and exact numerical averages are not included in this report. Accordingly, the results are presented as qualitative findings rather than as decimal scores that would imply a level of precision not available in the retained study material.

3. Overall Usability Result

The overall picture was positive. Users were generally able to enter the service, understand the interface, upload and prepare documents and complete the electronic-signature workflow without major usability barriers. The core product journey therefore performed well from a user-access perspective.

The feedback also showed that usability was not uniform across every part of the service. Friction increased when the user journey depended on additional identity-verification requirements or on blockchain transaction confirmation. The clearest example was QES onboarding, which was perceived as more demanding than the standard signing flow. ADA payment was technically functional but felt slower than the payment experience users were accustomed to from conventional online services.

This distinction is important: the study did not point to a fundamental usability problem in the docufi3d application. Instead, it identified specific advanced processes in which the user experience could be improved while preserving the simplicity of the core workflow.

4. Results Matrix

Tested area	Finding	Assessment
Getting started	Users were generally able to access and begin using docufi3d without significant difficulty.	Positive
General onboarding	The initial onboarding process was understandable and did not represent a significant barrier.	Positive
Navigation & UI	Users could generally find their way through the application and understand the next required steps.	Positive

Tested area	Finding	Assessment
Document upload	Uploading and preparing documents for signing worked smoothly.	Positive
Electronic signing	The core electronic-signature workflow was easy to understand and complete.	Positive / smooth
QES onboarding	Additional identification and verification steps introduced noticeably more friction than the standard signing process.	Improvement required
Pay-per-use	The ability to use docufi3d without a recurring subscription worked well and supported straightforward access.	Positive
Payment process	The general payment journey was broadly understandable and worked as intended.	Generally positive
ADA payment	ADA payment worked technically, but confirmation time was perceived as too slow compared with conventional online payment methods.	Functional, but too slow
Overall usability	The overall experience was positive; the main friction points were concentrated in specific additional processes.	Positive

5. Detailed Findings

5.1 Getting Started and Initial Access

The first interaction with a digital service is a critical usability point because users have not yet developed familiarity with the interface or terminology. The feedback indicated that docufi3d provided a generally accessible entry point. Users were able to begin the process without significant difficulties, supporting the conclusion that the service did not require extensive prior knowledge or training before it could be used.

5.2 General Onboarding

The general onboarding experience was positive. Participants were broadly able to understand what was expected of them and move from initial access into the product workflow. This is relevant because a technically capable signing service can still create a barrier if account setup or initial guidance is too complicated. The study did not identify general onboarding as a major source of friction.

5.3 Navigation and User Interface

Navigation and interface feedback was also positive. Users were generally able to understand where they were in the process and what they needed to do next. This suggests that the core information architecture and sequence of actions supported task completion rather than forcing users to learn a complex application structure before signing a document.

5.4 Document Upload and Preparation

Uploading and preparing documents formed an important transition from general platform access to the actual signing task. This part of the workflow was experienced as smooth. The feedback therefore supported the usability of one of docufi3d's central access points: moving a document into a state in which it could be electronically signed without creating unnecessary procedural complexity.

5.5 Electronic Signing

The core electronic-signature process was one of the strongest elements of the user journey. Participants were generally able to understand and complete the signing process. The study therefore separated the usability of signing itself from the more complex processes surrounding certain signature levels. This distinction became particularly relevant when evaluating QES.

5.6 QES Onboarding

QES onboarding was the clearest area in which users experienced additional friction. A Qualified Electronic Signature requires additional identity and verification steps, making the journey inherently more demanding than a basic electronic-signature flow. The feedback showed that these additional steps were noticeable to users and that the onboarding experience required further optimization. The finding did not indicate that electronic signing itself was difficult; rather, the additional identity journey associated with QES was the principal usability issue identified in the study.

5.7 Pay-per-Use

The pay-per-use model performed well from a usability perspective. Users could access the required functionality without first committing to a recurring subscription. This reduced commercial friction and was particularly suitable for occasional users or users wishing to try the service before making a longer-term commitment. In usability terms, the commercial model supported access rather than creating an additional barrier.

5.8 General Payment Process

The general payment process was broadly understood and functioned as intended. Payment therefore did not emerge as a general obstacle to using docufi3d. However, the study also demonstrated that the experience could differ depending on the payment method, with ADA representing a distinct case because transaction confirmation depended on blockchain processing.

5.9 ADA Payment

ADA payment was functional, but the user experience was affected by confirmation time. Users compared the waiting period with the near-immediate feedback commonly associated with conventional online payment methods. The resulting issue was therefore less about whether the payment succeeded and more about perceived speed and certainty during processing. This pointed to two UX priorities: reducing avoidable waiting time where technically possible and providing clearer transaction-status information while confirmation was pending.

5.10 Overall Usability

Taken together, the findings indicate a positive overall usability picture. The fundamental docufi3d journey - access, navigation, document handling and electronic signing - was generally smooth. The most significant friction occurred at the edges of the core experience, particularly where additional regulatory or technical processes were introduced. This provided a clear direction for product improvement without calling the usability of the core application into question.

6. User-Friendly Access Points

A central objective of the study was to understand whether docufi3d offered user-friendly access points to electronic-signature functionality. The feedback supported four principal access points.

Simple initial access

Users could begin using the service without a significant learning barrier.

Understandable core workflow

Navigation, document upload, preparation and signing followed a generally comprehensible sequence.

Pay-per-use access

Users could use the service without first entering a recurring subscription, reducing commercial friction.

Accessible signing functionality

The core signing process could be completed without specialist technical knowledge.

7. Areas for Improvement

7.1 QES Onboarding

The priority improvement area was the QES onboarding journey. The additional identification and verification requirements made this flow noticeably more complex than the standard signing journey. Further development should therefore focus on clearer guidance, better expectation management and a more seamless transition between the signing process and the required identity-verification steps.

The study suggests that improvements in this area could have a disproportionate effect on perceived usability because QES is an advanced trust function. Users who have already experienced a simple document workflow are likely to notice additional steps more strongly when they move into QES.

7.2 ADA Payment Experience

The second clear improvement area was the ADA payment experience. The payment method itself was functional, but confirmation took longer than users expected. A stronger user experience would therefore require both technical and communication improvements: where possible, processing should be optimized, while the interface should clearly show that a transaction is pending, what is happening and when the user can expect confirmation.

8. Product Implications

The findings provided a practical development direction. The product did not require a fundamental redesign of its core signing journey. Instead, the priority was to preserve the simplicity of the successful core flow while improving the advanced processes around it.

For QES, this meant reducing perceived complexity around identification and onboarding. For ADA payments, it meant improving the experience during transaction confirmation. Pay-per-use, by contrast, was validated as a useful access mechanism and should be retained as a low-friction commercial option.

The study also demonstrated why usability should be assessed across the complete user journey rather than only at the point of signing. Access, identity, payment and confirmation can materially influence whether a technically successful signing service is perceived as easy to use.

9. Conclusion

The docufi3d usability study conducted in July and August 2025 demonstrated a generally positive user experience and user-friendly access to the platform's core functionality. Thirty users participated and 25 completed the full questionnaire, resulting in a completion rate of 83.3%.

The core workflow - getting started, navigating the platform, uploading and preparing documents and completing electronic signatures - generally worked smoothly. The pay-per-use model also performed well and reduced the need for users to enter a subscription before using the service.

At the same time, the study produced actionable feedback. QES onboarding was the main usability area requiring improvement because the additional identification and verification steps introduced more friction than the standard signing flow. ADA payment was technically functional but comparatively slow from the user's perspective.

Overall, the study confirmed that docufi3d provided user-friendly access points to electronic-signature functionality while identifying specific advanced processes for further optimization.

Study conclusion

Core usability positive. User-friendly access confirmed. QES onboarding and ADA payment experience identified as the principal areas for improvement.
